Computing  $p$ -Values  
for  $t$  Tests

Practical (Economic)  
versus Statistical  
Significance

Confidence  
Intervals

Testing  
Multiple  
Exclusion

**Goal:** We want to test hypothesis about the parameters  $\beta_j$  in the population regression model.

We want to know whether the true parameter  $\beta_j = \text{some value (your hypothesis)}$ .

- In order to do that, we will need to add a final assumption **MLR.6**. We will obtain the **Classical Linear Model (CLM)**

## Motivation

Sampling  
Distributions  
of the OLS  
Estimators

Testing  
Hypotheses  
About a Single  
Population  
Parameter

Testing Against  
One-Sided  
Alternatives

Testing Against  
Two-Sided  
Alternatives

Testing Other  
Hypotheses about  
the  $\beta_j$

Computing  $p$ -Values  
for  $t$  Tests

Practical (Economic)  
versus Statistical  
Significance

Confidence  
Intervals

Testing  
Multiple  
Exclusion

**MLR.1:**  $y = \beta_0 + \beta_1x_1 + \beta_2x_2 + \dots + \beta_kx_k + u$

**MLR.2:** random sampling from the population

**MLR.3:** no perfect collinearity in the sample

**MLR.4:**  $E(u|x_1, \dots, x_k) = E(u) = 0$  (exogenous explanatory variables)

**MLR.5:**  $Var(u|x_1, \dots, x_k) = Var(u) = \sigma^2$  (homoskedasticity)

**MLR.1 - MLR.4:** Needed for unbiasedness of OLS:

$$E(\hat{\beta}_j) = \beta_j$$

**MLR.1 - MLR.5:** Needed to compute  $Var(\hat{\beta}_j)$ :

$$Var(\hat{\beta}_j) = \frac{\sigma^2}{SST_j(1 - R_j^2)}$$

$$\hat{\sigma}^2 = \frac{SSR}{(n - k - 1)}$$

and for efficiency of OLS  $\Rightarrow$  **BLUE**.

Motivation

Sampling  
Distributions  
of the OLS  
Estimators

Testing

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- Now we need to know the full sampling distribution of the  $\hat{\beta}_j$ .
- The **Gauss-Markov assumptions** don't tell us anything about these distributions.
- Based on our models, (conditional on  $\{(x_{i1}, \dots, x_{ik}) : i = 1, \dots, n\}$ ) we need to have  $dist(\hat{\beta}_j) = f(dist(u))$ , i.e.,

$$\hat{\beta}_j \sim pdf(u)$$

- That's why we need one more assumption.

Motivation

Sampling  
Distributions  
of the OLS  
Estimators

Significance

Confidence  
Intervals

Testing  
Multiple  
Exclusion

## MRL.6 (Normality)

The population error  $u$  is independent of the explanatory variables  $(x_1, \dots, x_k)$  and is normally distributed with mean zero and variance  $\sigma^2$ :

$$u \sim \text{Normal}(0, \sigma^2)$$

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

**MLR.1 - MLR.4**  $\rightarrow$  unbiasedness of OLS

**Gauss-Markov assumptions:** **MLR.1 - MLR.4** + **MLR.5** (homoskedastic errors)

**Classical Linear Model (CLM):** **Gauss-Markov** + **MLR.6** (Normally distributed errors)

$$u \sim \text{Normal}(0, \sigma^2)$$

- Strongest assumption.
- **MLR.6** implies  $\Rightarrow$  zero conditional mean (**MLR.4**) and homoskedasticity (**MLR.5**)
- Now we have full independence between  $u$  and  $(x_1, x_2, \dots, x_k)$  (*not just mean and variance independence*)
- Reason to call  $x_j$  **independent variables**.
- Recall the Normal distribution properties (see slides for **Appendix B**).

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

Figure:  $f(y|x)$  with homoskedastic normal errors, i.e.,  $u \sim N(0, \sigma^2)$

- Property of a **Normal distribution**: if  $W \sim Normal$  then  $a + bW \sim Normal$  for constants  $a$  and  $b$ .

- What we are saying is that for normal r.v.s, any linear combination of them is also normally distributed.
- Because the  $u_i$  are *independent and identically distributed (iid)* as  $Normal(0, \sigma^2)$

$$\hat{\beta}_j = \beta_j + \sum_{i=1}^n w_{ij}u_i \sim Normal(\beta_j, Var(\hat{\beta}_j))$$

- Then we can apply the Central Limit Theorem.

Testing Multiple Exclusion

## Theorem: Normal Sampling Distributions

Under the **CLM** assumptions, conditional on the sample outcomes of the explanatory variables,

$$\hat{\beta}_j \sim \text{Normal}(\beta_j, \text{Var}(\hat{\beta}_j))$$

and so

$$\frac{\hat{\beta}_j - \beta_j}{\text{sd}(\hat{\beta}_j)} \sim \text{Normal}(0, 1)$$

## Theorem: $t$ Distribution for Standardized Estimators

Under the **CLM** assumptions,

$$\frac{\hat{\beta}_j - \beta_j}{se(\hat{\beta}_j)} \sim t_{n-k-1} = t_{df}$$

where  $k + 1$  is the number of unknown parameter in the population model, and  $n - k - 1$  is the degrees of freedom (df).

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- The  $t$  distribution also has a bell shape, but is more spread out than the  $Normal(0, 1)$ .

- As  $df \rightarrow \infty$ ,

$$t_{df} \rightarrow Normal(0, 1)$$

- The difference is practically small for  $df > 120$ .
- See a  $t$  table.
- The next graph plots a standard normal pdf against a  $t_6$  pdf.

Motivation

Sampling Distributions of the OLS Estimators

**Testing Hypotheses About a Single Population Parameter**

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

Figure: The pdfs of a standard normal and a  $t_6$

- We use the result on the  $t$  distribution to test the null hypothesis that  $x_j$  has no partial effect on  $y$ :

$$H_0 : \beta_j = 0$$

$$lwage = \beta_0 + \beta_1 educ + \beta_2 exper + \beta_3 tenure + u$$

$$H_0 : \beta_2 = 0$$

- **Interpretation of what we are doing:** Once we control for education and time on the current job (*tenure*), total workforce experience has no affect on  $lwage = \log(wage)$ .

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- To test

$$H_0 : \beta_j = 0$$

we use the **t statistic** (or **t ratio**),

$$t_{\hat{\beta}_j} = \frac{\hat{\beta}_j}{se(\hat{\beta}_j)}$$

- In virtually all cases  $\hat{\beta}_j$  is not exactly equal to zero.
- When we use  $t_{\hat{\beta}_j}$ , we are measuring how far  $\hat{\beta}_j$  is from zero *relative to its standard error*.

- First consider the alternative

$$H_1 : \beta_j > 0$$

which means the null is effectively

$$H_0 : \beta_j \leq 0$$

- Using a positive one-sided alternative, if we reject  $\beta_j = 0$ , then we reject any  $\beta_j < 0$ , too.
- We often just state  $H_0 : \beta_j = 0$  and act like we do not care about negative values.

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- Because  $se(\hat{\beta}_j) > 0$ ,  $t_{\hat{\beta}_j}$  always has the same sign as  $\hat{\beta}_j$ .
- If the estimated coefficient  $\hat{\beta}_j$  is negative, it provides no evidence against  $H_0$  in favor of  $H_1 : \beta_j > 0$ .
- If  $\hat{\beta}_j$  is positive, the question is: How big does  $t_{\hat{\beta}_j} = \hat{\beta}_j / se(\hat{\beta}_j)$  have to be before we conclude  $H_0$  is “unlikely”?
- Let's review the Error Types in Statistics.

# Testing Against One-Sided Alternatives

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

1. Choose a null hypothesis:  $H_0 : \beta_j = 0$  (or  $H_0 : \beta_j \leq 0$ )

2. Choose an alternative hypothesis:  $H_1 : \beta_j > 0$

3. Choose a **significance level**  $\alpha$  (or simply **level**, or **size**) for the test.

That is, the probability of rejecting the null hypothesis when it is in fact true. (Type I Error).

Suppose we use 5%, so the probability of committing a Type I error is .05.

4. Obtain the critical value,  $c > 0$ , so that the **rejection rule**

$$t_{\hat{\beta}_j} > c$$

leads to a 5% level test.

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- The key is that, *under the null hypothesis*,

$$t_{\hat{\beta}_j} \sim t_{n-k-1} = t_{df}$$

and this is what we use to obtain the critical value,  $c$ .

- Suppose  $df = 28$  and we use a 5% test.
- Find the **critical value** in a t-table. (table).

# Testing Against One-Sided Alternatives

Numbers in each row of the table are values on a  $t$ -distribution with ( $df$ ) degrees of freedom for selected right-tail (greater-than) probabilities ( $p$ ).

Testing  
Multiple  
Exclusion

- So, with  $df = 28$ , the rejection rule for  $H_0 : \beta_j = 0$  against  $H_1 : \beta_j > 0$ , at the 5% level, is

$$t_{\hat{\beta}_j} > 1.701$$

We need a  $t$  statistic greater than 1.701 to conclude there is enough evidence against  $H_0$ .

- If  $t_{\hat{\beta}_j} \leq 1.701$ , we fail to reject  $H_0$  against  $H_1$  at the 5% significance level.

# Testing Against One-Sided Alternatives

- Suppose  $df = 28$ , but we want to carry out the test at a different significance level (often 10% level or the 1% level).

Numbers in each row of the table are values on a  $t$ -distribution with ( $df$ ) degrees of freedom for selected right-tail (greater-than) probabilities ( $p$ ).

df/p	0.40	0.25	0.10	0.05	0.025	0.01	0.005	0.0005

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

If we want to reduce the probability of Type I error, we must increase the critical value (so we reject the null less often).

- If we reject at, say, the 1% level, then we must also reject at any larger level.
- If we fail to reject at, say, the 10% level – so that  $t_{\hat{\beta}_j} \leq 1.313$  – then we will fail to reject at any smaller level.

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- With large sample sizes – certain when  $df > 120$  – we can use critical values from the standard normal distribution.

$$c_{.10} = 1.282$$

$$c_{.05} = 1.645$$

$$c_{.01} = 2.326$$

which we can round to 1.28, 1.65, and 2.36, respectively. The value 1.65 is especially common for a one-tailed test.

- Recall our **wage** model example:

$$\log(\text{wage}) = \beta_0 + \beta_1 \text{educ} + \beta_2 \text{exper} + \beta_3 \text{tenure} + u$$

- First, let's label the parameters with the variable names:  $\beta_{\text{educ}}$ ,  $\beta_{\text{exper}}$ , and  $\beta_{\text{tenure}}$
- We would like to test:

$$H_0 : \beta_{\text{exper}} = 0$$

**Interpretation:** We are testing if workforce experience has no effect on a wage once education and tenure have been accounted for.

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- What is the  $t_{exper}$ ?

$$t_{exper} = \frac{0.004}{0.002} = 2.00$$

- Now what do you do with this number?
- How many  $df$  do we have?
- Which table could I use?
- Using a standard normal table: the one-sided critical value at the 5% level, 1.645.

## Statistical Significance X Economic Importance/Interpretation

- So “ $\hat{\beta}_{exper}$  is **statistically significant**” at 5% level significance level (one-sided test).
- The estimated effect of *exper*, which is its **economic importance** should be interpreted as: another year of experience, holding *educ* and *tenure* fixed, is estimated to be worth about 0.4%.

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- For the negative one-sided alternative,

$$H_0 : \beta_j \geq 0$$

$$H_1 : \beta_j < 0$$

we use a symmetric rule. But the rejection rule is

$$t_{\hat{\beta}_j} < -c$$

where  $c$  is chosen in the same way as in the positive case.

# Testing Against One-Sided Alternatives

- With  $df = 28$  and we want to test at a 5% significance level, what is the critical value?

Numbers in each row of the table are values on a  $t$ -distribution with ( $df$ ) degrees of freedom for selected right-tail (greater-than) probabilities ( $p$ ).

df/p	0.40	0.25	0.10	0.05	0.025	0.01	0.005	0.0005

## Reminder about Testing

- Our hypotheses involve the unknown population values,  $\beta_j$ .
- If in a our set of data we obtain, say,  $\hat{\beta}_j = 2.75$ , we do not write the null hypothesis as

$$H_0 : 2.75 = 0$$

(which is obviously false).

Motivation

for  $t$  TestsPractical (Economic)  
versus Statistical  
SignificanceConfidence  
IntervalsTesting  
Multiple  
Exclusion

- Nor do we write

$$H_0 : \hat{\beta}_j = 0$$

(which is also false except in the very rare case that our estimate is exactly zero).

- We do not test hypotheses about the estimate! We know what it is once we collect the sample. We hypothesize about the unknown population value,  $\beta_j$ .

## Testing Against Two-Sided Alternatives

- Sometimes we do not know ahead of time whether a variable definitely has a positive effect or a negative effect.
- So, in this case the hypothesis should be written as:

$$H_0 : \beta_j = 0$$

$$H_1 : \beta_j \neq 0$$

- Testing against the **two-sided alternative** is usually the default. It prevents us from looking at the regression results and then deciding on the alternative.

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- Now we reject if  $\hat{\beta}_j$  is sufficiently large in magnitude, either positive or negative. We again use the  $t$  statistic  $t_{\hat{\beta}_j} = \hat{\beta}_j / se(\hat{\beta}_j)$ , but now the rejection rule is

## Two-tailed test

$$|t_{\hat{\beta}_j}| > c$$

- For example, if we use a 5% level test and  $df = 25$ , the two-tailed cv is 2.06. The two-tailed cv is, in this case, the 97.5 percentile in the  $t_{25}$  distribution. (Compare the one-tailed cv, about 1.71, the 95<sup>th</sup> percentile in the  $t_{25}$  distribution).

Confidence Intervals

Testing Multiple Exclusion

## Important observation

$$t_{\hat{\beta}_j} = \frac{\hat{\beta}_j}{se(\hat{\beta}_j)}$$

is *only* for  $H_0 : \beta_j = 0$ .

# Testing Other Hypotheses about the $\beta_j$

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- More generally, suppose the null is

$$H_0 : \beta_j = a_j$$

where we specify the value  $a_j$

- It is easy to extend the  $t$  statistic:

$$t = \frac{(\hat{\beta}_j - a_j)}{se(\hat{\beta}_j)}$$

The  $t$  statistic just measures how far our estimate,  $\hat{\beta}_j$ , is from the hypothesized value,  $a_j$ , relative to  $se(\hat{\beta}_j)$ .

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

## General expression for general $t$ testing

$$t = \frac{(\text{estimate} - \text{hypothesized value})}{\text{standard error}}$$

- The alternative can be one-sided or two-sided.
- We choose critical values in exactly the same way as before.

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- The traditional approach to testing, where we choose a significance level ahead of time, has a component of **arbitrariness**.
- Different researchers prefer different significance levels (10%, 5%, 1%).
- Committing to a significance level ahead of time can hide useful information about the outcome of hypothesis test.
- **Example:** (On white board)

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- Rather than have to specify a level ahead of time, or discuss different traditional significance levels (10%, 5%, 1%), it is better to answer the following question:

**Intuition:** Given the observed value of the  $t$  statistic, what is the *smallest* significance level at which I can reject  $H_0$ ?

- The smallest level at which the null can be rejected is known as the  $p$ -**value** of a test.

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

## $p$ -value

For  $t$  testing against a two-sided alternative,

$$p\text{-value} = P(|T| > |t|)$$

where  $t$  is the value of the  $t$  statistic and  $T$  is a random variable with the  $t_{df}$  distribution.

- The  $p$ -value is a probability, so it is between zero and one.

Motivation

Sampling

Hypotheses about  
the  $\beta_j$

Computing  $p$ -Values  
for  $t$  Tests

Practical (Economic)  
versus Statistical  
Significance

Confidence  
Intervals

Testing  
Multiple  
Exclusion

One way to think about the  $p$ -values is that it uses the observed statistic as the critical value, and then finds the significance level of the test using that critical value.

- Usually we just report  $p$ -values for two-sided alternatives.

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

## Mnemonic Device

*Small*  $p$ -values are evidence *against* the null hypothesis.

*Large*  $p$ -values provide little evidence *against* the null hypothesis.

**Intuition:**  $p$ -value is the probability of observing a statistic as extreme as we did if the null hypothesis is true.

Motivation

Computing  $p$ -Values  
for  $t$  Tests

Practical (Economic)  
versus Statistical  
Significance

Confidence  
Intervals

Testing  
Multiple  
Exclusion

- If  $p$ -value = .50, then there is a 50% chance of observing a  $t$  as large as we did (in absolute value). This is not enough evidence against  $H_0$ .
- If  $p$ -value = .001, then the chance of seeing a  $t$  statistic as extreme as we did is .1%.
- We can conclude that we got a very rare sample (*unlikely!*) or that the null hypothesis is very likely false.

Motivation

Sampling Distributions of the OLS Estimators

Significance

Confidence  
Intervals

Testing  
Multiple  
Exclusion

- $t$  testing is purely about *statistical significance*.
- It does not directly speak to the issue of whether a variable has a practically, or economically large effect.

**Practical (Economic) Significance** depends on the size (and sign) of  $\hat{\beta}_j$ .

**Statistical Significance** depends on  $t_{\hat{\beta}_j}$ .

Practical (Economic) versus Statistical Significance

**Confidence Intervals**

Testing Multiple Exclusion

- **Under the CLM assumptions**, rather than just testing hypotheses about parameters it is also useful to construct **confidence intervals** (also know as **interval estimates**).

**Intuition:** If you could obtain several random samples data, the **confidence interval** tells you that, for a 95% CI, your true  $\beta_j$  will lie in this interval  $[\beta_j^{lower}, \beta_j^{upper}]$  for 95% of the samples.

- We will construct CIs of the form

$$\hat{\beta}_j \pm c \cdot se(\hat{\beta}_j)$$

where  $c > 0$  is chosen based on the **confidence level**.

- We will use a 95% confidence level, in which case  $c$  comes from the 97.5 percentile in the  $t_{df}$  distribution.
- Therefore,  $c$  is the 5% critical value against a two-sided alternative.

Testing Multiple Exclusion

## Rule of Thumb

- For,  $df \geq 120$ , an approximate 95% CI is:

$$\hat{\beta}_j \pm 2 \cdot se(\hat{\beta}_j) \text{ or } \left[ \hat{\beta}_j - 2 \cdot se(\hat{\beta}_j), \hat{\beta}_j + 2 \cdot se(\hat{\beta}_j) \right]$$

- For small  $df$ , the exact percentiles should be obtained from a  $t$  table.

Testing  
Multiple  
Exclusion

A 95% CI means is that for 95% of the random samples that we draw from the population,

the interval we compute using the rule  $\hat{\beta}_j \pm c \cdot se(\hat{\beta}_j)$

will include the value  $\beta_j$ .

**But for a particular sample we do not know whether  $\beta_j$  is in the interval.**

- This is similar to the idea that unbiasedness of  $\hat{\beta}_j$  does *not* means that  $\hat{\beta}_j = \beta_j$ . Most of the time  $\hat{\beta}_j$  is not  $\beta_j$ . Unbiasedness means  $E(\hat{\beta}_j) = \beta_j$ .

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple

- To test  $H_0$ , we need a **joint (multiple) hypotheses test**.
- A  $t$  statistic can be used for a single exclusion restriction; it does not take a stand on the values of the other parameters.
- We are considering the alternative to be:

$$H_1 : H_0 \text{ is not true}$$

- So,  $H_1$  means **at least one** of betas is different from zero.

# Testing Multiple Exclusion Restrictions

Motivation

## $F$ test

Does the  $SSR$  increase proportionately by enough to conclude the restrictions under  $H_0$  are false?

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple

- In the general model:

$$y = \beta_0 + \beta_1 x_1 + \dots + \beta_k x_k + u$$

we want to test that the last  $q$  variables can be excluded:

$$H_0 : \beta_{k-q+1} = 0, \dots, \beta_k = 0$$

- We get  $SSR_{ur}$  from estimating the full model.

- The restricted model we estimate to get  $SSR_r$  drops the last  $q$  variables ( $q$  exclusion restrictions):

$$y = \beta_0 + \beta_1 x_1 + \dots + \beta_{k-q} x_{k-q} + u$$

- The **F statistic** uses a degrees of freedom adjustment. In general, we have

$$F = \frac{(SSR_r - SSR_{ur}) / (df_r - df_{ur})}{SSR_{ur} / df_{ur}} = \frac{(SSR_r - SSR_{ur}) / q}{SSR_{ur} / (n - k - 1)}$$

where  $q$  is the number of exclusion restrictions imposed under the null ( $q = 2$  in our example).

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple

$$q = \text{numerator df} = df_r - df_{ur}$$

$$n - k - 1 = \text{denominator df} = df_{ur}$$

- The denominator of the  $F$  statistic,  $SSR_{ur}/df_{ur}$ , is the unbiased estimator of  $\sigma^2$  from the unrestricted model.
- Note that  $F \geq 0$ , and  $F > 0$  virtually always holds.
- As a computational device, sometimes the formula

$$F = \frac{(SSR_r - SSR_{ur})}{SSR_{ur}} \cdot \frac{(n - k - 1)}{q}$$

is useful.

- Using classical testing, the rejection rule is of the form

$$F > c$$

where  $c$  is an appropriately chosen **critical value**.

## Distribution of $F$ statistic

Under  $H_0$  (the  $q$  exclusion restrictions)

$$F \sim F_{q, n-k-1}$$

i.e., it has an  $F$  distribution with  $(q, n - k - 1)$  degrees of freedom.

- Recall the  $F$  distribution (see slides for **Appendix B**).

- Confidence Intervals
- Testing Multiple

- Suppose  $q = 3$  and  $n - k - 1 = df_{ur} = 60$ . Then the 5% cv is 2.76.

**Question:** Is there a way to compute the  $F$  statistic with the information reported in the standard output from any econometric/statistical package?

- The  $R$ -squared is always reported.
- The SSR is not reported most of the time.
- It turns out that  $F$  tests for exclusion restrictions can be computed entirely from the  $R$ -squareds for the restricted and unrestricted models.
- Notice that,

$$SSR_r = (1 - R_r^2)SST$$

$$SSR_{ur} = (1 - R_{ur}^2)SST$$

- Motivation

the  $\beta_j$

Computing  $p$ -Values  
for  $t$  Tests

Practical (Economic)  
versus Statistical  
Significance

Confidence  
Intervals

Testing  
Multiple  
Exclusion

- We say that *exper*, and *tenure* are **jointly statistically significant** (or just **jointly significant**), in this case, at any small significance level we want.
- The  $F$  statistic does not allow us to tell which of the population coefficients are different from zero. And the  $t$  statistics do not help much in this example.

## The $F$ Statistic for Overall Significance of a Regression

- The  $F$  statistic in the **R** output tests a very special null hypothesis.
- In the model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \dots + \beta_k x_k + 0$$

the null is that **all slope coefficients are zero**, i.e.,

$$H_0 : \beta_1 = 0, \beta_2 = 0, \dots, \beta_k = 0$$

- This means that none of the  $x_j$  helps explain  $y$ .
- If we cannot reject this null, we have found no factors that explain  $y$ .

Motivation

Sampling Distributions of the OLS Estimators

Testing Hypotheses About a Single Population Parameter

Testing Against One-Sided Alternatives

Testing Against Two-Sided Alternatives

Testing Other Hypotheses about the  $\beta_j$

Computing  $p$ -Values for  $t$  Tests

Practical (Economic) versus Statistical Significance

Confidence Intervals

Testing Multiple Exclusion

- For this test,

$R_r^2 = 0$  (no explanatory variables under  $H_0$ ).

$R_{ur}^2 = R^2$  from the regression.

$$F = \frac{R^2/k}{(1 - R^2)/(n - k - 1)} = \frac{R^2}{(1 - R^2)} \cdot \frac{(n - k - 1)}{k}$$

Confidence  
Intervals

Testing  
Multiple  
Exclusion

- As  $R^2$  increases, so does  $F$ .
- A small  $R^2$  can lead  $F$  to be significant.
- If the  $df = n - k - 1$  is large (because of large  $n$ ),  $F$  can be large even with a “small”  $R^2$ .
- Increasing  $k$  decreases  $F$ .
